Introduction

This report documents a service-learning project that evaluated the economic and social effects of natural disasters on farmers in and around San Luis Obispo, California, through applied anthropological ethnographic research. In partnership with the Scripps Howard Center for Civic Engagement (SHCfCE) and funded by a Learn and Serve America Grant, Douglas Hume (Assistant Professor of Anthropology at Northern Kentucky University [NKU]) and six NKU undergraduate anthropology students (Brandy Blust, Matthew Buttacavoli, Timothy Carpenter, Emela Halilovic, Kevin Talbert, and Michael Washburn), who were part of the Applied Environmental Anthropology Research Group (AEARG) at NKU, interviewed farmers in the greater San Luis Obispo area during the winter intersession of 2009-10. Farmers were interviewed to discover the following:

1. how do farmers define natural disasters;
2. how do these natural disasters affect the farmers’ quality of life (in particular what aspects of health, education and economic behavior change as a result of natural disasters); and
3. what networks exist to provide social and economic support in response to natural disasters?

Methods

In preparation for this research project, six of the nine student applicants were selected based on academic merit and seniority in the Anthropology Program at NKU. These six students enrolled in an independent studies course during the second session of fall 2009 in which they were trained in ethnographic interview methods (McCurdy, Spradley, and Shandy 2004) and logistical planning for the project was completed. In addition to ethnographic methods, students were trained in research ethics involving human subjects in accord with the Institutional Review Board requirements at NKU to ensure that the specific farmers with whom we spoke with were protected from any ramifications from their participation in this research.

During the fall preparation and winter intersession fieldwork in California, the SHCfCE administered the Learn and Serve America Grant. Michael Walther, SHCfCE Civic Engagement Coordinator Assistant, managed the financial and logistical support that SHCfCE provided for this project. Christina Gunn, SHCfCE Secretary, coordinated all travel arrangements. Chatodd Floyd, AmeriCorps VISTA Volunteer, contacted potential informants in California and organized a schedule of farm visits and farmer interviews.

The field research was conducted from December 20 2009 to January 9 2010. AEARG members collected ethnographic data by interviewing 62 farmers in and around San Luis Obispo, California. The informants were interviewed at their work sites, whether on farms or at farmers’ markets. Interviews at farms were scheduled whereas interviews at farmers’ markets were arranged on site. The number of students conducting each interview ranged from one to four students per informant with the norm being two students per informant. The field notes the students took both during and after the interviews augmented the digital audio recording of interviews. Douglas Hume, the instructor and AEARG Director,
documented the events and places that were visited though field notes and digital photographs. The digital audio files, transcribed notations, and photographs collected in the field were electronically archived for future use during data analysis.

After transcribing the 62 interviews, the digital audio recordings were destroyed per the Informed Consent Statement (see Appendix I). The transcriptions were then analyzed by word count and the identification of informant statements that addressed one or more of the three themes of this research: 1) definitions of natural disasters and the effect of these natural disasters on 2) quality of life, and 3) support networks. Initial results of the text analysis were presented by the students at NKU’s Celebration of Undergraduate Research (see Appendix II). The final report was written during the 2010 spring semester.

Findings

In general, farmers reported that while natural disasters are a constant risk to the economic viability of their farms, they were optimistic that their knowledge of the environment would enable them to adopt strategies that would minimize or mitigate the risks and enhance the likelihood of crop success in a dynamic environment with variable conditions. Though the farmers differed in their definition of what comprised a farming community, they were in agreement that the best strategy to overcome adversity was to rely upon the farming community, rather than governmental aid. The term natural disaster is most commonly defined as being a highly destructive environmental phenomenon (e.g., volcano eruptions, earthquakes, and tsunamis) that indiscriminately impacts a large geographic area, farmers expand this definition to include events that are more localized (e.g., microclimates) and have targeted impacts that are inclusive of those things that are crop specific (e.g., frosts and diseases). In the following sections, the specific findings on how natural disasters affect quality of life, how farmers use networks of social and economic support, and definitions of natural disasters are described.

Definition of Natural Disasters

When asked about their classification of natural disasters, several farmers described the popular culture schema of natural disasters, which include large, catastrophic events that can create widespread damage to structures. Though many farmers lose as much as 20 percent of produce to pests, this occurrence is not considered a natural disaster but a cost of business, an acceptable and expected loss which is figured into total yearly production. As one farmer said, a natural disaster is “any damage that is unwarranted or unexpected” beyond this expected loss. Many environmental and biological disruptions cause production loss, but only a few are considered natural disasters. Though there are variations in farmers’ individual definitions of natural disasters, there appears to be a general agreement that a natural disaster occurs when a natural event has a significant catastrophic disruption to some portion of the processes of growing, harvesting or transporting agricultural products to the consumer.

Descriptions of types of natural disasters by the farmers interviewed fit into two broad categories: environmental and biological natural disasters. A working definition of natural disasters varies depending on what individual farmers have experienced in the
past and what they view as future threats to their production. When asked, the informants were able to provide a list of natural disasters that have an immediate effect on agricultural production, many of which do not necessarily meet the criteria of the standard definition of natural disasters, as “any event or force of nature that has catastrophic consequences, such as avalanche, earthquake, flood, forest fire, hurricane, lightning, tornado, tsunami, and volcanic eruption” (Dictionary.com 2010).

Of the two categories of natural disasters, environmental disasters were more commonly cited as being problematic for farmers. The most common types of environmental disasters are weather related events. Temperature related events such as freezes and frosts were implicated most frequently by farmers as causing the most intensive crop damage. Wind damage was mentioned approximately half as frequently, but was mostly limited to damage to trees, especially if the trees were in fruit. High winds could also cause structural damage, mostly to greenhouses, though not commonly cited as causing significant crop damage. Storms, however, with both high winds and hail can be devastating to fruit crops. Informants reported that sunburn of fruits and vegetables may also damage crops, but occurred less often than other weather related crop damage. Flooding can also have adverse affects on farm production. For example, one farmer lost an entire broccoli crop to flooding while two other farmers claimed flooding impeded their ability to bring produce to market. Natural disasters, in this case flooding, do not only impact production, but also distribution of produce. In cases when drought was mentioned, most farmers spoke about the current four-year drought that they fear will continue to impact their ability to grow crops, at least, in the near future. The farmers often mentioned earthquakes and fires, but farmers reported that these types of disasters had little effect on the farms, as earthquakes only cause minor damage to structures, not crops, and wild fires affecting farms are rare in this region of California.

According to farmers, while the frequency of biological disasters may be higher than environmental disasters, they seem to be less catastrophic. This may be due to the preventability or treatability of biological factors. Animal activity, such as small herbivores, gophers and squirrels, were cited as most common type of biological natural disaster that affects crops. Large herbivores, such as deer and wild boars, can cause widespread damage to ground crops and young trees, but are preventable with proper fencing. Carnivores are a problem for those farmers who also raise livestock, with mountain lions and bears being reported as responsible for livestock deaths. Insect pest activity, such as aphids and husk flies, may decrease production or damage produce so that it may not be sold. Informants reported that birds cause direct damage to grapes and berries through consumption or by spreading diseases. Birds and other biological pests may be prevented by various means (e.g., traps and netting) and do not pose a large threat to crops, but do raise the cost of production.

Disease-causing agents are another subtype of a biological disaster. Viruses and fungi are more commonly cited as affecting fruit and nut trees than annual vegetable produce and, therefore, long-term and costly investment is needed to protect fruit and nut trees, which take many years to mature. Disease was cited to have the potential to destroy an entire orchard and is the main reason one informant refused to adopt solely organic
practices even though she believed that organic farming was better for the environment and people that consume the produce.

A few farmers who were interviewed indicated that artificial (e.g., economic and political) events amplify the affects of natural disasters. While not a category of natural disaster, amplifying events may have many of the same economic results. Farmers often cited the current economy as the cause for lower sales. Bank loans and crop insurance become more difficult to obtain during a recession. Over-regulation may prevent the preferred treatment of a disease or infestation. Finally, water laws due to drought concerns may limit the amount of water that the farmer can give to his or her plants and lead to further crop issues.

Quality of Life

The quality of life of the farmers that were interviewed is affected in both preparing for and responding to perceived natural disasters. For example, extreme events can directly compromise health through disrupting water supply or access to medical facilities as well as generally increasing the likelihood of accidental injury. Loss of crops can mean loss of variety and nutrition in diet by the loss of foods consumed by the farmers and loss of income with which to purchase food. Prolonged financial difficulties cause long-term stress, which compromises biological immune systems and contribute to a large variety of other health concerns. Resources redirected to disaster response or preparedness (e.g., purchasing and installing greenhouses, removing flammable brush, installing new wells and irrigation) are unavailable for routine healthcare or health insurance.

It is believed that when farmers utilize sustainable farming techniques (e.g., biodynamics, permaculture, organic farming), they may protect against future natural disasters and improve the health of individuals working on the farm and consuming their produce. In addition, farms growing a variety of crops in hopes of preventing total crop loss in the event of a natural disaster can result in reduced outflows of chemical pollutants, having an ancillary benefit to the health of the surrounding environment in which the farmer lives. These sustainable practices are seen as a substitute or partial substitute for healthcare insurance by introducing a nutritious diet that benefits the farmer and the community by reducing the future cost of medical expenses.

Changes in farmers’ economic behavior brought about by the impacts of natural disasters are expressed by increased spending of preventative measures, short-term economic loss due to decline in crop production, and impact of crop loss on the local economy. The increased spending on preventive measures (e.g., green houses, fertilizers, and irrigation) leads to short-term financial loss and, at the same time, an investment for future crop protection enabling long-term financial security. The severity of the event determines if the farmer experiences short-term and/or long-term economic loss due to crop reduction. Depending on the duration, the inability to meet consumer demand can be a short-term financial loss that can lead to a long-term economic hardship. The consumer may opt to seek other suppliers if the farmer is unable to supply a product in a timely and consistent manner, thus affecting the farmer and the local economy. The businesses with which
farmers rely on (e.g., farm stores and labor contractors) also have a stake in the farming community and any altered state of economic behavior on a farm has an effect on the local economy.

Farmers may go years without experiencing a governmentally recognized natural disaster while continuously coping with challenging weather events that some consider normal, and others consider natural disasters. Farmers’ experience equips them with the knowledge to manage these individually catastrophic events and minimize potential damage. Occasionally an unusually extreme and unforeseen natural disaster causes unanticipated damage and economic loss. These natural disasters reveal previously unknown vulnerabilities. Unexpected losses motivate individual farmers to modify their farming practices. Seeking appropriate responses, these farmers engage in new learning behaviors. These behaviors include devising experimental tests and agricultural techniques, researching appropriate practices on the Internet, consulting the farming community, and occasionally seek advice from government agricultural agencies. These efforts may also result in relief provided by the community in the form of donated labor. If such relief is needed and available, it usually arrives quickly due to the connectedness of local farm communities.

Social and Economic Support

For the most part, the San Luis Obispo area’s farmers’ main resources during natural disasters are themselves. Most often, farmers reported the reasons for this self-reliance was due to having a personal ethic of independence or having not received either adequate or timely reimbursement from the government assistance programs when aid was requested. One farmer said that he did not feel that it was ethically correct to take money from the government saying: “it’s my choice [to take on the risk of farming]. I mean it’s like going to Vegas. I mean a person goes to Vegas it shouldn't be anyone else’s responsibility to bail them out.” Several of the farmers stated that they believed the government takes too long to provide assistance or that it was too much work for the small amount of aid that was awarded. Several farmers also stated that another reason they did not use the government was because of their lack of knowledge about the availability of assistance. Some farmers, who did apply for aid, still did not receive any, as they did not meet the governmental requirements for aid distribution because their organic farm was small-scale and did not rely upon irrigation. As one farmer stated, “I was so furious when I walked out of the USDA’s office. I was like okay, so because I am doing the right thing [being organic,] I don’t qualify for any support.”

Farmers stated that they attempted to prevent or lessen the effects of natural disasters by their choice of location, diversity of crops, and timing of harvests. Farmers reported that it was important to understand the characteristics of the land both for choosing the location of fields, but also for the best time to plant and harvest particular varieties of crops. There appears to be agreement among farmers that by understanding the land and plants one can reduce the impact natural disasters have on crops. One method that was reported to work for small-scale farmers was diversifying their crops to ensure that a minor natural disaster (e.g., isolated frost) would only affect part of the farm’s total crop.
yield. One farmer explained that “real farmers [that are] really connected to nature are self insured [because] you can’t be connected to nature and have a mono-culture.”

In another attempt to create support mechanisms against farm losses due to natural disasters, farmers utilized farmers’ markets and Community Supported Agriculture (CSA) cooperatives to find customers to purchase their produce as well as making lasting connections with the community at large. Merchants and farmers interviewed at each of the farmers’ markets expressed how they were pleased with the opportunities that the farmers’ markets gave them to sell their produce on a weekly basis and create lasting relationships with their customers, who are often referred to as regulars. Many of the customers were willing to support local farmers by paying slightly more for the local produce at the markets or CSAs versus buying similar produce at the grocery store. Many small-scale farmers expressed that farmers’ markets and CSAs are the only real alternative to selling their produce wholesale. Community members who take part in a CSA often wish to support locally grown produce more than those who shop at the farmers’ markets.

There is a variety of ways farmers rely on other community members as well as other farmers, most often, physically, financially, and/or intellectually. Many of the farmers that were interviewed reported that they asked other farmers in their community to help with physical labor on the farm due to unforeseen circumstances such as a sudden frost during which crops needed to be covered quickly. Farmers also stated that they received financial assistance from other farmers and community members through fundraisers. Finally, farmers described how they shared ideas with each other to enhance each other’s farming techniques. This was most common with farmers that were devoting all or part of their crop to organic produce.

Similar to how farmers in the area relied on the community, they also relied on family and friends financially, physically, and intellectually, as well as emotionally. Many farmers said that they asked for physical labor help and borrowed money from their family and friends in time of need. Friends and family were a valuable resource to many of the farmers, whether they needed help starting a new farm or on a well-established farm with the daily work. Friends and family were also described as an outlet for the emotional struggles that occur during farming in general as well as preparing for or recovering from natural disasters.

**Conclusion**

This service-learning research project has found preliminary answers to the three broad research questions investigated with farmers in the San Luis Obispo area. First, farmers consider a much broader set of phenomena to be categorized as natural disasters than the standard definition contains. Second, natural disasters, in their extended meaning as used by farmers, affect farmers’ quality of life mostly economically, which then may affect health and, to a lesser extent, education. Finally, farmers choose to respond to natural disasters by being self-reliant, building cooperative communities, and seeking aid from their families. Much more work is needed to understand the variation that exists among the San Luis
Obispo area farmers in their understanding of and response to natural disasters. However, the reliance on internal support (e.g., self, community, and family) rather than external support (e.g., federal, state or other local aid agencies) suggests that a community-based system of agriculture may be a better fit for this region than a top-down regional agencies approach for managing risks and damage from natural disasters.
